

Interim Guide to Draft Data Products and Potential Methods to Describe the Five Components of Ecological Importance from the Important Ecological Area Framework in the 2016 Northeast Ocean Plan

DRAFT

May 9, 2017

The Northeast Regional Planning Body (RPB) has been working with the Marine Life Data and Analysis Team (MDAT) to organize existing data and develop new draft products that could apply to each of the five components from the Important Ecological Area Framework (IEAs). This interim guide provides an overview of those draft data products and the methods for developing them, including references for each. Each of the data products, the methods used to develop those products, and the organization of these products within the IEA Framework are draft. Therefore, everything in this interim guide should be construed as a work-in-progress.

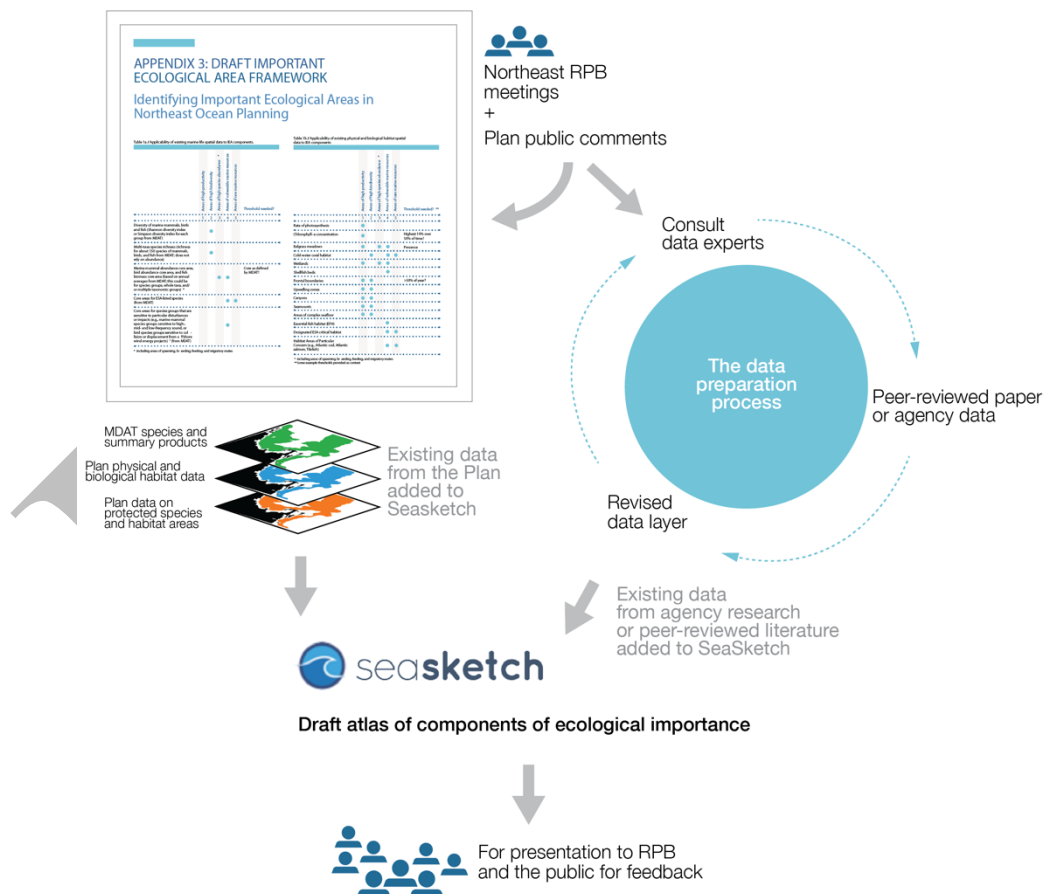

For each draft data layer (first column of the tables), the interim guide notes the unit of measure and the spatial resolution (second and third columns). Additional information about each draft data layer, such as the temporal resolution, or the analytical method used to derive the layer—if not provided in the data layer name—is provided in the “Reference(s)” column (last column in the tables).

In addition, the RPB and MDAT provide the following notes about the over 100 datasets described in this guide:

- These data reflect *observed and/or sampled* marine life and habitats; therefore, characterizations of productivity, diversity, richness, abundance, and rarity (and likely other characterizations) should not be interpreted to summarize or represent these metrics for the *total ecosystem*, but may provide meaningful estimates based on current scientific understanding.
- There are clear differences in scale and observational effort among taxa, habitats, and geographies (i.e., nearshore, offshore, off the shelf) which need to be considered in the context of the “representativeness” of each dataset.
- To provide structure and context for the data, it was often helpful to organize datasets into categories within each component (e.g., data layers relevant to high abundance and data layers relevant to important life history stages for Component 3). These categories are shown in rows within each Component table in blue text.
- Some of the data layers reflect different ways to represent a single concept (for example, species richness and Gini-Simpson index are two ways to represent biodiversity).
- There are several ecosystem features for which there are currently limited or no data, including benthic productivity, kelp forests, large-bodied/pelagic fishes, benthic invertebrate communities, and sea turtles.

Since the Northeast Ocean Plan was completed, the RPB and MDAT revised the data for productivity and biodiversity (Components 1 and 2) according to feedback received during discussions with the RPB, the Ecosystem-based Management (EBM) Work Group, and the public at the public EBM Work Group meeting held in Boston, MA in July 2016. The RPB and MDAT have also begun considering methods and developing or incorporating data products that are pertinent to abundance, vulnerability and rarity (Components 3-5). This work has been the result of several organizations' sharing and coordination, including NOAA Northeast Fisheries Science Center (primary and secondary productivity data), the New England Fishery Management Council (habitat vulnerability from the Swept-Area-Seabed-Impact model, draft deep sea coral zones), the Mid-Atlantic Fishery Management Council (deep sea coral protection zones), and NOAA National Centers for Coastal and Ocean Science (coral habitat suitability models, productivity proxies).

The process by which this work was and is being conducted is shown in the graphic below. The work focused on assembling all available (published, peer-reviewed) data and established methods that are relevant to each component; ignoring (for now) any redundancy among datasets. As a result, there are now more than 100 individual data layers that potentially address ecological importance under the five components, many of which are already included on the Northeast Ocean Data Portal, but each of which needs to be reviewed for their appropriateness in this context.

Component 1: Areas of high productivity

The NOAA Northeast Fisheries Science Center (NEFSC) will be the primary data provider for the data in this component. The RPB continues to work with NEFSC staff to determine which available datasets best characterize productivity for the [US Northeast Shelf Large Marine Ecosystem](#). The RPB expects to receive data representing: spring bloom frequency, magnitude and start day (1998-2015) from Friedland et al. 2015; primary productivity season means (1997-2015); and total zooplankton “biovolume” interpolations from NEFSC data.

Component 2: Areas of high biodiversity

Biodiversity products were produced as part of the Marine life Data and Analysis Team (MDAT) mapping effort and include sampled/observed marine mammal, bird, and fish species. The intention for this component is to first display taxonomic metrics of biodiversity because 1) they are complete, and 2) they may adequately characterize patterns in biodiversity. Longer-term, there is a potential option to develop maps of functional diversity that include metrics of trophic richness (provided now as a proof of concept) but could also include metrics of mobility type, habitat preference, size, body form, and life span. There is a large body of functional trait research that could be used to choose metrics and assign taxa/species to trait categories (for example see <http://www.marinespecies.org/traits/>).

Available online: http://esriurl.com/5754 .

Component 3: Areas of high abundance

Abundance products for marine mammals, birds, and fish are readily available from the MDAT mapping effort, and they were produced with two different methods: simple total abundance maps per taxa and core abundance/biomass area richness per taxa. The core abundance/biomass area richness methodology and products were reviewed by the Marine life Work Groups and EBM Work Group in February 2016 and will be submitted for peer-review in a scientific journal in 2017. A ranked relative abundance approach is another method tested by MDAT that has promise because relative abundances can be readily compared among taxa. Currently, ranked relative abundances are included for individual taxa separately. Abundance products for benthic invertebrates are summarized on the grid used for the [New England Fishery Management Council \(NEFMC\) Swept-Area-Seabed-Impact \(SASI\) analysis](#) grid (10km x 10km), as made available by the data provider (University of Massachusetts School for Marine Science and Technology (SMAST)). Longer-term, the RPB is working with SMAST to re-map these observations on a 1-2km grid.

Component 4: Areas of vulnerable marine resources

Data relevant to vulnerable marine resources come from many sources. Several sources were related to a management or regulatory framework designed to protect the resource; e.g., Critical Habitats defined under the Endangered Species Act. Layers were also derived from studies or efforts to quantify species’ sensitivity to a particular stressor; e.g., the maps of avian species with higher collision sensitivity due to offshore renewable energy. Therefore, the available observational data and the chosen mapping approach may be skewed toward a particular concern/impact and less representative of more general inherent vulnerability. As a result, the layers in this category range in their ability to characterize species’ fragility, inherent sensitivity, and sensitivity to specific stressors/disturbances.

For this Component, to date, the RPB has relied heavily on existing data on the Northeast Ocean Data Portal, and also obtained new data from the [New England Fishery Management Council's SASI analyses](#) and [deep sea corals work](#), as well as the [Mid-Atlantic Fishery Management Council's deep sea corals work](#).

Component 5: Areas of rare marine resources

For this component, rarity is parsed into the rarity of species at regional and global scales. To date and due to data availability, the RPB has relied primarily on Endangered Species Act status to determine the species that were relevant to this component. Layers representing individual species/group abundance are derived from the MDAT mapping effort. All of the following datasets are already publicly available on the Northeast Ocean Data Portal.
